Clean Coal Technologies Are Improving Air Quality in Kentucky

A new Emissions and Air Quality Trends Report for 1999-2011, published by independent consultants Alpine Geophysics and ENVIRON International, documents the substantial decreases in air pollutants from coal-fueled electric generation and other sources in Kentucky and across the United States. These emission reductions are yielding significant air quality improvements in both urban smog (ozone) and fine particulate matter (PM2.5).

Highlights of Alpine/ENVIRON's report for Kentucky:

- Kentucky's coal-fueled power plants have reduced emissions of nitrogen oxides by 70 percent since 1999, compared with an average 50 percent reduction for all other sources.
- Coal-based electric generation accounted for 20 percent of Kentucky's total ozone-related emissions in 2011.

- The Alpine Geophysics/ENVIRON report also documents the significant reductions since 1999 in
 emissions contributing to fine particulates sulfur dioxide, nitrogen oxides, volatile organic
 compounds (VOCs) and direct PM emissions. Kentucky's coal-based electric utilities have
 reduced these PM-related emissions by 65 percent since 1999, the largest reduction among all
 major source categories.
- These reductions in PM2.5- and smog-forming emissions by coal-based generators will help Kentucky to meet both the eight-hour ozone standard and new PM2.5 standard that EPA is now implementing.
- Investments in clean coal technologies by Kentucky's coal-based electric utilities are producing cleaner air for the benefit of all Kentucky citizens.

The June 2013 Alpine/ENVIRON emissions and air quality trends reports for 48 states and 5 regions are available at www.americaspower.org.
